investor brief

Benjamin a. Mowinckel — est. March 2026

Alexandria is a tribe of people who put their minds into writing so AI thinks with them, not for them.

Most AI investments cannot defend their terminal value. Alexandria's compounds with every model release — especially post-singularity.

the investment.

Five beliefs install the cheque.

1. *Most AI products are transition assets — value is the gap between model capability and user need; the gap closes with every release; value decays into the model.*

2. *Companies that survive are the ones where every model release amplifies the asset rather than absorbing it.*

3. *Alexandria's asset is a private, accumulating, machine-readable record of how a specific person thinks — sovereign to the user, unsynthesizable from outside, compounding across years that cannot be back-filled.*

4. *The strategic prize is the canonical write path and permission layer for those records — the convention slot, shape of WordPress, GitHub, Hugging Face. Winner-takes-most.*

5. *Coding throughput is not the constraint. Benjamin has personal runway through the end of 2026; distribution is the current constraint, and capital is needed before runway ends.*

Company infrastructure is cheap, and Benjamin has personal runway through the end of 2026. Investor routes are prepared now while he is still in San Francisco; conversations fire after two outside users complete setup and a first session without founder repair. *That proof lets the eventual round be set from evidence rather than pressure. Capital can fund the chosen 2027 runway, accelerate a distribution motion that works, and add the first public referee for the category. More model usage comes before bounded specialist engineering.*

the asset.

A structured, machine-readable record of who each user is — whatever they choose to put in it: worldview, values, mental models, taste, personal thoughts, decisions, blind spots, anything. **The product is the framework; the practice is theirs.** Some users run daily Socratic sessions; others keep journals, log decisions, dump streams of consciousness, build their own ritual. **Sovereign to the user. Portable across every AI provider. Worth more from every better model.**

The record cannot be back-filled. Inbox-scraping reaches what the user does, never what they mean. Five years of capture cannot be compressed into a six-month rush. **The compounding is the years.**

The product reached v3; real-user hardening begins now. *One paste, local files on the user's own machine, two integration points fire whenever the user talks to an AI — capture and inject. The tool is free; membership is $30/month after a 30-day trial, or free while three referred friends remain active.* The live questions are who starts, returns and pays, and what breaks when they do.

the survival test.

Does this company get better or worse when the next model drops?

Most AI products degrade — coding assistants, productivity wrappers, content generators absorbed into each model release. **That is not terminal value. That is an exit timeline dressed as a multiple.**

Alexandria gets better. *Each user's record is private, accumulating, unsynthesizable from public sources. Better models extract deeper signal from the same record.* Every release is a tailwind.

In April 2026 Andrej Karpathy publicly described this architecture — raw data compiled into structured markdown, incrementally enhanced, queries that compound back into the knowledge base — and said *"there is room here for an incredible new product."* **Alexandria had already shipped it.** The category will exist. The open question is who owns the convention.

the stake.

The demand for this asset is structural, not aspirational.

AI commoditises capability — strength, intelligence, empathy in sequence. *The cultural premium on human authorship inflates as commoditisation deepens.* **The grandmother's blanket is the grandmother's blanket because she made it.** A factory robot weaving the identical blanket is not the same blanket. The people who develop the *who* behind the work capture the premium.

Everyone else competes on artifacts AI can replicate.

The deeper risk is decay. *AI removes the demand on cognition; cognition only develops to the level of demand placed on it; the faculty that would notice the loss is the faculty that has weakened.* WALL-E for the body is science fiction. **WALL-E for the mind is the default trajectory.**

Keep thinking. *That is the rally and the practice. The gym is yours; Alexandria is what's built around it.*

---

the moat.

Technical moats die when intelligence commoditises. Even the data isn't a moat — ***Alexandria is sovereign by design; any individual user can take their files and walk away at zero cost.*** *That's deliberate.*

The defensibility is one layer up: coordination. *Alexandria only works as the read* ***and*** *write path for personal thought — writers chase readers; readers chase writers; both terminate on the same place.* Once that's where the network gathers, individual exits don't change anything — the value lives in everyone else still being there. **Displacing Alexandria requires getting the entire network to switch simultaneously. That doesn't happen.**

This is how every durable protocol has worked. HTTP, SMTP, GitHub, Hugging Face — open by design, technically replaceable, practically untouchable. **The scarce asset in a world of cheap intelligence is not capability; it is coordination.** Alexandria's bet is to be the coordination point for personal cognition.

Three reinforcing forms of that coordination:

1. Convention. *The canonical place where thoughtful people host their cognitive records — "build it on WordPress," "push it to GitHub," "host your mind on Alexandria" ("Strava for thought" is the pitch line, not the product name; "open and forkable, like GitHub" is a throwaway aside, never the frame).* Once the convention settles, individual exits don't shift it; until it settles, there is nothing to defend. **Apple can build the tool; Apple cannot build the cathedral.** *Winner-takes-most once held —*

and the 12–36 month race to hold it is now.

2. Network. *Your circle being on Alexandria means your AI can read their frames when planning with or about them; their AI reads yours.* The friend's-mind primitive makes recruitment a self-interested act — *invite your circle for your own benefit.* A clone can host identical files but starts with no population.

3. Integration. *Every AI tool, agent, and app that reads from the user's local Alexandria directory is another terminal point the coordination terminates on.* Today: Claude Code, Cursor, Codex, Grok CLI hooks. Tomorrow: every personalised app and agent. **The user can always leave; the ecosystem points back because the coordination is here.**

Two objections answered:

"Frontier labs will build this." They won't. **Sovereignty is the opposite of their business model** — every dollar spent on neutral user-side infrastructure is a dollar not spent on the next training run. Cross-tool credibility requires a neutrality no single lab can offer. *Every memory feature labs ship validates the demand without competing with it.*

"BCI will read inner speech and kill the asset." It won't. Decoded neural activity is **generically readable but not individually meaningful** — meaning requires the user's own reference frame to interpret. Stanford's Willett (2025) hit 62 words per minute of decoded inner speech; even at perfect readout, the signal is uninterpretable without the frame. **BCIs are the bridge; Alexandria builds what crosses it.**

the business.

Two revenue streams compound on the same users.

Membership. *The tool and methodology are free; membership is $30/month after a 30-day trial, or free while three referred friends remain active.* Prosumer comparables (Cursor, ChatGPT Pro, Notion AI) show that people willingly pay $20–$60/month for tools they actually value. Stands alone. **Break-even at 4 paying members.**

Platform. *Users grant other services permissioned access to their Alexandria record — opt-in, revocable per service.* AI labs pay for alignment and personalisation research data. Consumer apps pay to know users who knowingly want to be known (meditation, therapy, dating, productivity, healthcare). **The user monetises their own frame; Alexandria captures a clearing fee on every transaction.** *Independent of membership count.*

If	Then
~100K paying members × $50/m settled	~$60M ARR
Platform / integration revenue	~$40M+ ARR
Combined at standard 10× SaaS multiple	**$1B+ valuation**

If membership saturates short of 100K, platform carries the upside. If platform stays narrow, membership scales on its own. Single-mode failure risk drops.

the founder.

At pre-seed, the moat is the founder. **The cheque is on the person.**

Benjamin a. Mowinckel. Norwegian-American, 26. Eton, Princeton, Norwegian military, brief stint at Verdane. Currently in San Francisco.

No conventional technical credentials. No previous ventures. The company is the proof: **he directed the entire stack with coding agents, reached v3, and began external manual onboarding on**

24 August 2026.

Benjamin's irreducible edge is the framing and philosophy. Coding is cheap, and he expects to remain the technical owner through coding agents. If faster scale exposes a specific reliability, security, or hardening problem, he can spend more on model usage or hire a paid one-off or part-time specialist.

	$/m
Company opex	$100
Founder bare minimum	$500
Founder safe monthly	$5,000

The company costs little to operate, and Benjamin has personal runway through the end of 2026. *Investor conversations start after two clean outside-user transfers; the eventual amount is set from the desired 2027 runway, first-user evidence, and any distribution motion that earns funding.*

Princeton cohort, all under 27, frontier of their fields: *the founder of the RL company Anthropic uses for computer-use agents; one of the youngest macro pod leaders at Millennium; a Bain Capital associate; an Oxford PhD with the Larry Ellison Institute; the head of the Norway branch of a US defence company; a US Army Ranger candidate.* **The thinking happens inside this conversation.**

In his own words: *"I could be wrong. I doubt it. The company costs $100 a month. If I am wrong, the world loses nothing. If I am right and nobody builds this, the world loses something it did not know it needed. Either way, I am building it. I can see myself working on this for the rest of my life — through the transition and after."*

what could go wrong.

Demand untested at scale. Acknowledged. *The first users answer it while also exposing the real reliability work. The bridge buys enough founder time to run that experiment properly; larger capital scales only what the experiment proves.*

Convention slot taken first. Real risk. *A better-funded entrant could land "host your mind on X" before us.* Mitigated by move-as-if-12, public artifacts shipping continuously, and founding-cohort velocity. **Not eliminated — that's why the 12-month window is a strategic constraint, not a stylistic one.**

TAM does not answer adoption. *Depending on the category boundary, the theoretical market can be everyone:* the individual tool combines personal context, memory and cognitive development, and the collective can in principle appeal broadly too. But universality does not prove that people will start, stay, pay or join. The costs are small but real — five minutes, attention and the articulation the mental gym requires. The company has to measure those choices directly. Once the record compounds, leaving feels like loss. **The acquisition problem is making the bet legible and testing behaviour, not arguing from a TAM slide.**

Capture bottleneck. *Most users have no digital interior.* The daily session is itself the capture mechanism. *Capture infrastructure shipped — desktop + iOS one-tap.*

Solo founder, no track record. *Mitigated by the company being its own demonstration of the thesis, the Princeton cohort, and the Karpathy-validated architecture. Not eliminated.*

Alexandria asks the user for marginal everything — marginal money, marginal time, marginal attention. Downside is zero. **The bet is conviction, not proof.**

the ask.

A small round before the end of 2026. *Set the exact amount from the desired 2027 runway and first-user evidence.* Capital funds runway and proven distribution. Engineering stays founder-led; model spend comes before bounded specialist help.

Returns are the long call option. Legacy is the more certain payoff.

Every standard that mattered had a first funder. HTTP had CERN. Ethereum had Joe Lubin. The early internet had DARPA. Alexandria is the cognitive layer of AI — the standard that makes AI think *with* you, not *for* you — and right now it is open. *The firm whose name attaches becomes the* *firm that goes on the page about how humans preserved thinking through the AI transition. In thirty years that page exists. The question is who is on it.*

Athens, Rome, America, Alexandria. **America protects the right to think. Alexandria protects the ability.**

Set the angels free.
